To

A. Chapman, M.D.

Respected Sir,

Difficult operations require able hands. So universal is the application of this remark, that it will hold good in every department of science and mechanics.

No one for instance will commence an undertaking, to accomplish which great exertion is necessary, unless he is conscious that he possesses a sufficient degree of muscular power. So in science, the solution of abstruse questions is ought to be committed to competent persons.

(10)

If this be true, and the accumulated expe-
 rience of ages proves it so, what apology shall
 I offer for engaging in a subject, which notwith-
 standing all that has been said, is still undeni-
 ably, wrapped in the most profound and mysterious
 obscurity;—a subject on which the sun of science
 has scarcely shed a single beam of light; and
 a subject which has baffled all the attempts
 and defeated all the endeavours of the most
 able, expert and ingenious physiologists to
 unravel its intricacies. Confessedly, Sir, the
 Modus Operandi of Medicine is obscure, and
 requires for its explanation talents of a superior
 cast. And although my undaunting genius
 would not dare advance a single opinion of its
 own on the subject, yet I must I may say,
 without danger of incurring the imputation
 of Pedantry, that I can compile the various
 sentiments which different authors hold, and

[Faint, illegible handwriting on lined paper, likely bleed-through from the reverse side.]

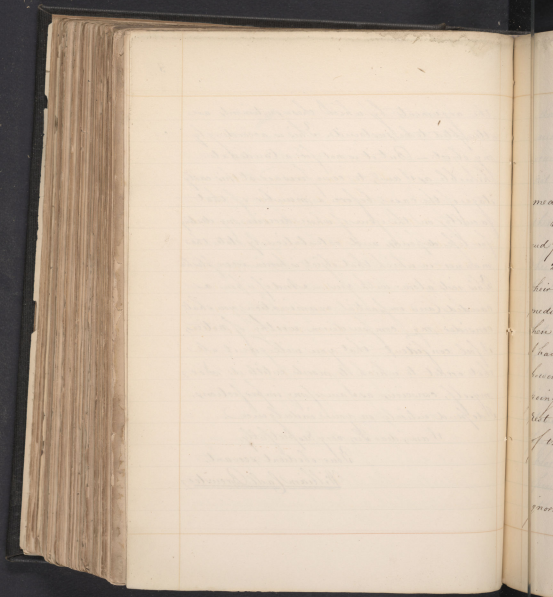

the ar
thougl

the arguments by which these sentiments are attempted to be sustained. This is accordingly my object. — But it is not for a Candidate humbly as I am, to come forward at this early stage of the case, before a member of that faculty on the issue of whose decision my destiny for life depends, and ostentatiously state the manner in which that object is herein accomplished. This rests alone with you. — And if upon a candid and impartial examination, you shall consider my compendium worthy of notice, I feel confident that you will give it all that credit to which its merits entitle it. But, myself, conscious as I am of my imperfections, I depend entirely on your indulgence.

I am, dear Sir, very respectfully,

Your obedient servant,

William Laidlaw Brewster,

To explain the operation of
 medicines, two doctrines at present prevail:

1st Medicines are absorbed into the circulation,
 and produce their effect by means of the blood.

2nd Medicines operate alone on the solids,
 their influence being extended through the
 medium of sympathy. Against the first of
 these hypotheses I most candidly confess that
 I have a personal prejudice. This circumstance
 however shall not in the least prevent me from
 going over all the grounds on which its partisans
 rest their defence for the establishment
 of their doctrine.

In the dark ages of
 ignorance and delusion, when no right way

Known but a sacred veneration for old opinions,
 and a blind devotion to magisterial authority
 science lay almost dormant. We are therefore
 not to be surprised to hear of the prevalence of
 many strange and gratuitous notions. Among
 these the blood was supposed to undergo changes
 in quantity, consistence, temperature &c. Hence
 the origin of the terms *Insipidant*, *Attenuant*,
Diluant, *Refrigerant* &c. Opinions, however,
 so totally groundless were destined to have
 but a temporary continuance. The increase
 of Knowledge soon exposed their fallacy, and
 accordingly they were abandoned by all
 discerning, scientific Philosophers. Notwith-
 standing this however, there are still those who
 profess to believe that certain medicines are
 absorbed into the circulation. Such an
 opinion appears to me altogether inconsistent
 with the nature of the blood; and I do

[Faint, illegible handwriting on the left page, likely bleed-through from the reverse side.]

[Faint handwriting on the right page, likely bleed-through from the reverse side.]

6
maintain that it never has, and never can
be proved by any direct or positive evidence.

Every substance that is taken into
the stomach, whether a aliment or medicine is
at once exposed to the powers of digestion. By
this process all the original compounds are
decomposed, and one complete homogeneous mass
is formed. And it is evident that no medicines
can reach the seat of absorption in their
nascent state, and of course cannot be absorbed
as medicine. This would seem to strike the
doctrine at the very root. To get over the insur-
mountable difficulty, we must either suppose
that there are Lactals in the stomach, or that
the gastric juice has no power of operating
upon medicines; the very converse of both of
which is known to be the case.

absor

troch

case for

and

might

we ca

a sub

ment

when

itself

vicin

would

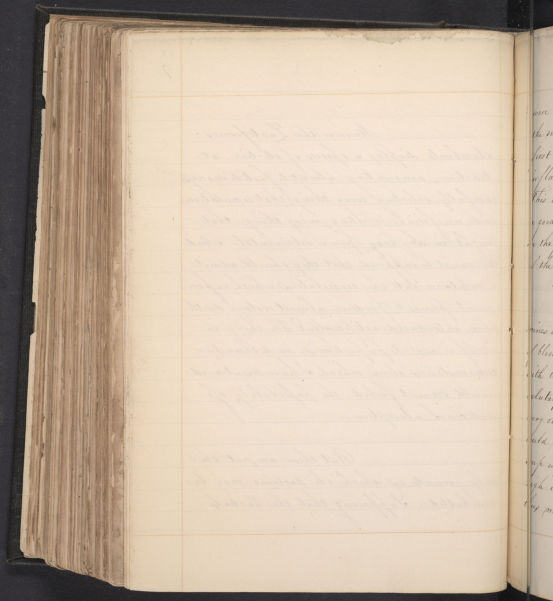

Medic

only

comba

Moreover the Lactiferous
absorbents display a species of elective at-
traction, amounting almost to fastidiousness,
carefully selecting every thing that is nutritious,
and uniformly rejecting every thing that
might in any way prove detrimental. And
how can it be supposed that they should admit
a substance into the circulation which experi-
ment proves to produce almost certain death
when introduced artificially? The thing in
itself is next to preposterous; and these two
circumstances alone which I have mentioned
would seem to forbid the possibility of
Medicinal absorption.

But these are not the
only grounds on which the doctrine may be
combated. Supposing that the Lactals

were incapable of rejecting what is injurious—
the substance absorbed would penetrate to the
first conglobate gland, which would take on
inflammation, and arrest its further progress.
This we knew perfectly well to be the case, and
a good exemplification of the position we have
in the production of Gums from the absorption
of the Syphilitic virus.

But admitting that medi-
cines do enter the circulation, the whole mass
of blood in this case, must be equally charged
with the substances, and of course while a
salutary action is going on in a diseased organ,
every other part of the system must suffer. This
could not fail to be the case. When a bowl of
soup is placed on the table, if it is seasoned very
high with pepper, salt, nutmeg &c, the substance
thus medicated, may suit one palate, while

he c
 every
 reason
 obvious
 as mo
 he de
 r an
 specu
 system
 a satis
 f
 well
 force
 would
 he
 have
 I as

perhaps it may disagree with all the rest of the company. This example, coarse as it is, seems very well to illustrate my meaning. The reasonableness of the supposition must be obvious to every impartial observer. Why shall a medicine after it has arrived in the blood be determined to any one part in preference to another; and why shall it not produce its peculiar effect on every organ in the whole system? Is this very natural interrogatory a satisfactory answer never has been given.

Moreover we know perfectly well that the effects of certain articles are perceived in a much shorter time than they would be, provided they were absorbed into the circulation. Examples of this fact we have in the almost instantaneous stimulus of ardent spirits, in the poisonous effects of

[Faint, illegible handwriting on the left page, likely bleed-through from the reverse side.]

[Faint, illegible handwriting on the right page, likely bleed-through from the reverse side.]

Opium, and the anti-febrile qualities of Cinchona.

Again, if medicines entered the blood, it is very reasonable to suppose that they should be found in that fluid. This however, does not appear to be the case. In an experiment, Dr. Wollaston gave a person a quantity of Prussiate of Potash: but after a lapse of four hours, upon an examination of the blood, no Prussiate was to be found in its serum. — In opposition to this however, we are told by Mr. Brande, one of most eminent chemists in Europe, that he administered Soda to a patient for a long time, and in a large quantity; and then (mirabile dictu!) he detected the substance in the blood; which he might have done, had his patient never seen a particle of Soda, much less taken it. It is perfectly well known that in a

sub
his
best
of p

natural state Soda is one of the constituents of blood: And I am astonished to find that so great a man should undertake to support a favourite doctrine on such flimsy evidence as this.

In addition to all this it may be stated that extraneous substances of any kind when injected into the circulation produce very serious consequences. The most bland articles, as milk, chyle &c. have been known to occasion distressing effects; and Bichat states that in several cases even a bubble of air caused immediate death. Innumerable experiments have been made on the subject with precisely similar results, so that this point appears to be pretty well settled. And besides, the most zealous upholders of the opposite doctrine do not hesitate to admit the

very
we are
so
with

ma
cap
ling

does
sub
the
that
the
so he
An o
rem

truth of the fact, though they attribute it to a very peculiar circumstance. The fact is, medicines are extraneous substances, and as such they have no business to circulate throughout the system with a vital fluid like the blood.

With such an overwhelming mass of evidence as this, what unconfiding sceptic can doubt of the operation of medicines being entirely independent of the Circulation? If such an one there were, let him have his doubts removed by the known fact that many substances produce their full effect though the heart and blood vessels be taken away: so that in this case they could not possibly enter the circulation. Experiments, the relation of which I am merely transcribing from a known source, and to which I may incidentally remark I am indebted for many of the ideas,

The lines erased in pages 13 & 14, were
denied by the Candidate, as intending
anything personal to one of the Pro-
fessors, who objected to the retaining
the paragraphs in the Thesis - It was
immediately agreed to by the Candidate
that it should be erased.

Alfred. - March 24th 1878

I have advanced in this treatise, of experiments I say, made by Whitt and Galland, and repeated by others equally respectable experimentalists, sufficiently confirm the truth of the fact above stated.

~~Notwithstanding all this however, there are still those who profess to believe that medicines enter the circulation and produce their effects in the way, and the profession I am warranted in saying is all. For I cannot think that in these enlightened days there are any who really believe the doctrine they endeavour to support. If they did, why do they not in some cases of Dysphagia and Stomachicoplegia the injection of medicines into the veins? This is a very natural interrogatory, and until it is answered, I am fully warranted in~~

~~Handwritten text, crossed out with a large X.~~

Handwritten text on the right margin, partially visible.

~~saying that they do not in fact believe their
own doctrines. It is more therefore from a
desire of maintaining extravagant and
favourite opinions than of benefiting science,
that these eccentric partisans labour to confound
sentiments which are totally incompatible and
altogether inconsistent with the known laws
of the human system. But without pursuing
this disagreeable enquiry any farther I shall
proceed to examine the weak grounds on which
the doctrine is attempted to be established.~~

Prior to this however, I may
remark what I have heretofore done, that
medicines have never been detected in the
circulation. The careful, well-conducted,
and very candid experiment, to which I formerly
alluded, made by Dr. Willaston, leaves no
doubt in this subject. Similar results have

invariably followed all subsequent attempts. In fact the most strenuous upholders of the doctrine do not pretend that they have ever traced medicines further than the Thoracic Duct, or at most, the Mesenteric vessels. And when we recollect that these experiments were made by men blinded by preconceived notions and determined at all events to support a favourite opinion, I think we need offer no apology for strongly doubting their validity. As for myself, casting forth as I do from the humble recesses of obscurity a dim glance on the all-resplendent Sun of science, I should not at all hesitate in pronouncing these statements wilful exaggerations, or in discrediting them authoritatively altogether. The men who performed these experiments, however respectable, it must be remembered had their own opinions to support. Placed in such circumstances, they could

[Faint, illegible handwriting, likely bleed-through from the reverse side of the page.]

[Faint, illegible handwriting on the right edge of the page, likely bleed-through from the reverse side.]

only see through the glass of bias: and what
was deficient in reality, their own fertile
imagination, were ever ready to supply.

Discarding then as I do
all evidence of direct experiment, I shall proceed
to examine some accessory circumstances which
it is supposed favour the supposition of
Medicinal Absorption.

It is well known that after
eating strong-smelling articles, such as Garlic,
Onions &c. the peculiar odour of these substances
is perceived in the breath: hence it is inferred
that they must have entered the blood. Such
a conclusion however, is entirely unwarrantable.
Every one must know that the substance might
give out its odour in the stomach as well as in
the open air: and that this odour might spread

by exhalation, or rise by specific levity up through the Oesophagus, and mingling with the breath, its properties might thus become perceptible to the sense of smell. This explanation is not at all forced. Analogy supports it. Thus in cases of ulcerations of the Tonsils or Fauces, or in case of a carious tooth, a disagreeable smell is evident in the breath. Now this fact is altogether independent of the Lungs. Besides the before-mentioned effects take place in a much shorter space of time than would have been occupied by the passage of the substances in question through the rout of the circulation. But what puts this matter beyond all reach of controversy, and completely establishes the explanation I have ventured to suggest, is that the odour of the above articles is perceived although in the act of respiration be entirely suspended. This experiment I have tried

repeatedly, and with invariable success.

The blackening of the skin by the internal exhibition of Nitrate of Silver has also been mentioned as a proof of medicinal absorption. But this must not be received too hastily. Analogy renders it highly probable that medicines are decomposed by the process of digestion into their primitive elements. In this state they may be absorbed into the circulation. But when thrown into the secretions or excretions, being removed beyond the control of the vital energies, chemical affinities are sometimes again brought into play, by which these substances are in part or wholly regenerated. Such may be the case with Nitrate of Silver. At any rate whether this explanation be received or not, certain it is that many substances are displayed in some of the

secretions which never existed in the blood. No
 one pretends ever to have discovered Uric acid
 in the blood, yet this substance is found in
 the Urine. In jaundice, the urine is tinged of
 a deep saffron colour; owing as it has been
 supposed to the absorption of Bile. But
 neither has the colour or taste of bile ever been
 perceived in the Serum of the blood, or Urine.
 Numerous other circumstances to the same
 purport might be mentioned: but these
 examples will suffice to show that because
 a substance is found in a particular situation,
 it is no proof that it must have passed there
 through the circulation in its original state.
 It was stated by one of the oldest Physiologists,
 Boerhaave, & Boerhaave, that Mercurial globules
 were actually seen in the Urine. Now can we
 for a moment suppose that a substance whose
 specific gravity is at least twelve times

[Faint, illegible handwriting in cursive script, likely bleed-through from the reverse side of the page.]

[Faint, illegible handwriting on the right edge of the page, possibly from the adjacent page.]

greater than that of the blood, could circulate with this fluid through all parts of the body? The idea is at once ridiculous and absurd. Besides, extraneous bodies are often found in different parts of the body. Last winter in dissecting a gentleman, a needle was discovered occupying one of the Lungs. We were told by the advocates of medicinal absorption that this needle could only have reached the pulmonary organs through the medium of the circulation? I mention this circumstance, not because I suppose there any so stupid as to believe the latter explanation, but merely to show to what ridiculous consequences the doctrine if extended would lead.

Another circumstance which has been supposed to favour the doctrine of medicinal absorption is that the

well
adapted
to the
purpose.

colouring matter of Rhubarb has been
 perceived in the Urine after the exhibition
 of this article. Now here I may very properly
 recur to the old interrogatory— if the Rhubarb
 passed the rent of the circulation, why is
 not its colour visible in the blood? This
 objection is supposed to be done away by
 answering that the Rhubarb is diffused
 through such a large mass of fluid, it is
 impossible that its properties should be perceptible,
 but that when condensed into a smaller
 compass in an excretion, as the urine, then
 its colour is rendered sensible. This explanation
 is not only a shy subterfuge, but it is an
 absolute untruth. To satisfy myself on this
 point, I made two or three experiments. In
 the first I took thirty-two pints of limpid
 colourless water into this I slowly introduced
 half a drachm of Rhubarb. Upon stirring

[Faint, mirrored handwriting, likely bleed-through from the reverse side of the page.]

the
yellow
gran
fun
sens
is the
met
doac
atua
whole
me p
the e
cons
mus
sup
being
just
why

the mixture, I perceived the whole had a yellow tinge. Again, I dropped a single grain of Rhubarb into a quart of water, and found that even this larger quantity was sensibly coloured. Now twenty-four pints is the medium quantity of blood generally met with in the human system: half a drachm therefore of Rhubarb, which is the usual dose, it is obvious ought to colour the whole mass of circulating fluids. And when we recollect that the Serum, in which alone the colour could be perceived, does not constitute one half part of this blood, we must be struck with the fact that this fluid ought to have a deep tinge; the quantity being only twelve pints.

But if Rhubarb passed the point of the circulation to get to the bladder, why I may ask is it not perceptible in some

[Faint, mirrored handwriting, likely bleed-through from the reverse side of the page.]

[Faint handwriting visible on the right edge of the page, possibly from the adjacent page.]

of the other secretions, as well as the urine? Here we are very seriously told that the urine is an excretion, destined to carry off all superfluous matters, and that Rhubarb is among the substances of this description. And what I may inquire is the matter of perspiration? Certainly this is also an excretion, and being in a much smaller quantity than the urine, it should be much more deeply coloured. It follows therefore that Rhubarb, never, could have entered the blood.

But I will go a step farther. I am now to combat the doctrine on the broad ground that there is a direct communication between the Alimentary Canal and Bladder. This opinion would not appear improbable from the numerous anastomoses among the lymphatics of these parts. The supposition is also strengthened by the fact of the very speedy passage of

The first of these is the fact that the
 human mind is not a blank slate at birth
 but is filled with a vast amount of
 information that is acquired from the
 environment. This information is stored
 in the memory and is available for
 use when needed. The second fact is
 that the human mind is capable of
 learning from experience. This is done
 by comparing new information with
 information already stored in the
 memory. If the new information
 is found to be different from the
 information already stored, it is added
 to the memory. If it is found to be
 the same, it is not added. This process
 of learning from experience is called
 "learning by example." The third fact
 is that the human mind is capable of
 learning from observation. This is done
 by watching others perform a task and
 then imitating their actions. This
 process of learning from observation is
 called "learning by observation." The
 fourth fact is that the human mind
 is capable of learning from reading.
 This is done by reading books and
 articles and then applying the
 information to one's own life. This
 process of learning from reading is
 called "learning by reading." The
 fifth fact is that the human mind
 is capable of learning from listening.
 This is done by listening to lectures
 and talks and then applying the
 information to one's own life. This
 process of learning from listening is
 called "learning by listening." The
 sixth fact is that the human mind
 is capable of learning from doing.
 This is done by actually performing
 a task and then reflecting on the
 experience. This process of learning
 from doing is called "learning by
 doing." The seventh fact is that the
 human mind is capable of learning
 from reflection. This is done by
 thinking about one's own experiences
 and then drawing conclusions from
 them. This process of learning from
 reflection is called "learning by
 reflection." The eighth fact is that
 the human mind is capable of learning
 from dreams. This is done by
 reflecting on the events that occur
 in one's dreams and then applying
 the lessons learned to one's waking
 life. This process of learning from
 dreams is called "learning by
 dreaming." The ninth fact is that
 the human mind is capable of learning
 from intuition. This is done by
 trusting one's gut feelings and then
 acting on them. This process of
 learning from intuition is called
 "learning by intuition." The tenth
 fact is that the human mind is
 capable of learning from love. This
 is done by loving others and then
 learning from their example. This
 process of learning from love is
 called "learning by love."

certain acidulous water. But what puts the matter beyond all possible doubt, is that although a ligature be passed around both the Nerves, yet in due time the bladder will be filled with urine. The fact therefore of Whinbark being found in the urine, is far from proving medicinal absorption, rather tends to a contrary belief, in as much as it demonstrates that substances can be found in apparently unnatural positions without ever entering the blood.

It has been said that after the liberal internal exhibition of Vineture of Cantharids, the skin has been observed to become vesicated. Admitting the truth of the fact, and I am by no means disposed to doubt it, it does not at all prove that the medicine passed into the blood vessels in order to arrive at the skin. In how can we believe that a

[Faint, illegible handwriting, likely bleed-through from the reverse side]

[Faint, illegible handwriting on the right edge of the page]

substance so acid and irritating as Cantharides could mix itself with a vital fluid like the blood, and move in immediate contact with the delicate internal coats of the arteries and veins with impunity, and yet vesicate the comparatively dense and tough texture of the skin? This idea is stranger, and appears altogether inconsistent and unnatural. I am not here bound as before to demonstrate a direct passage from the stomach to the skin. It is enough that the substance never entered the blood itself, and this I think I have sufficiently shown.

There are many other arguments used for the same purpose. But the answers to them are alike simple, so that it will not be necessary to enter into any more minutiae of detail. The supposed proofs of medicinal absorption are weak and illusory; and

[Faint, illegible handwriting visible through the paper, likely bleed-through from the reverse side.]

[Faint, illegible handwriting visible on the edge of the adjacent page.]

as well might its advocates attempt to

"Twain with force of lead,

Or hew down oaks with rushes,"

as undertake the sustentation of their doctrine on such slender grounds as these they have advanced.

It follows therefore from the above remarks that we are to reject altogether the medication of the blood as the means by which remedies impregious are made of the human system.

What then remains? Are we to fold our arms in quietude and ease, content with the present attainments of science, nor rush headlong (and blind-folded) into practice? Thanks to the brightness of genius, neither of these unhappy alternatives now remains. In a beautiful modern theory we have a full and satisfactory explanation of all the phenomena

concerned in the *Modus Operandi* of medicines. This doctrine, though simple, and well-substantiated, has never the less passed through the fiery ordeal of rigid criticism. The ignorant have broken out against it in the most bitter invectives, while even the learned have received it with silent contempt, or cold disdain. The jealous have raised their feeble voices in its disparagement, and "Sympathy" has been the by-word and ridicule of every taunting slanderer and malicious satirist. Notwithstanding this however truth will prevail, and up from the altitudinated walls of detraction and jealousy it shall rise victorious, arrayed in all the grandeur of magnificence, and glory of triumph.

But it is time to enter upon the subject under consideration. The doctrine to which I alluded in the former paragraph, and

for the

for the support of which, if any it wants, I shall
 lend my feeble assistance, alleges that medicines
 "all act by exciting a local impression, which is
 extended through the medium of sympathy." By
 Sympathy, or consociation of parts is to be understood,
 that property of the animal economy by which
 an impression made on one part is propagated
 to another. Thus head-ache is caused by
 gastric derangement; itching of the nose, by worms;
 pain in the shoulder by Rheumatic affections; pain
 in the knee by disease of the Hip-joint &c. The
 existence of these sympathetic actions is as
 indubitable as it is necessary. The only question
 is, in what does sympathy consist? Notwithstanding
 all the researches of Physiologists, little or no
 light has been thrown on this interesting subject.
 "The word Sympathy," says Bichat, "is only a
 veil for our ignorance in respect to the relation
 of the organs to each other." The existence of

[Faint, illegible handwriting across the page, likely bleed-through from the reverse side.]

19
can
the
m
B
off

m

Sympathy is known only from its effects, the cause being not at all understood. In employing the term therefore, says Dr. Chastman, "we mean only to denote a principle or power, of which we know nothing, except from the experience of its effects, the precise essence or nature being occult and concealed". The term we use to designate the "particular effect, is of no importance, if we but know what ideas we wish to convey. The word Sympathy", says Richat, "is of but little consequence, provided what it expresses be understood".

The cause then of Sympathy being concealed, but its existence undoubted, it becomes a matter of enquiry, in what manner are these impressions extended? This medium of conveyance is very naturally supposed to be the nerves. When we recollect the extensive distribution and intimate connection of these organs, we must

[Faint, illegible handwriting on lined paper, likely bleed-through from the reverse side.]

be
cal
But
how

rice
H
brin
the
the
the
with
comm
then
syste
thene
actio
net
comm

be sensible of the facility with which impressions could be conveyed to every part of the system.

But if the nerves be the means of conveyance, how does it happen that sympathetic actions take place between parts which have no visible nervous communication whatever?

Here it is to be recollected that the nervous system brings every sentient and irritable part, under the immediate influence of the Sensorium commune, the brain; and that therefore, all the parts of the body have a continuous nervous connection with each other, through the medium of this common centre of feeling. It is, not surprising, then, that impressions made on one part of the system may be extended to the brain, and from thence to another part, and that thus sympathetic actions may take place between parts that have not apparently the most distant nervous connection.

[Faint, illegible handwriting, likely bleed-through from the reverse side]

In the
 I have
 the

 Opera

 medic

These explain a long series will
prepare the way for the remaining observations
I have yet to make, and which will conclude
this imperfect treatise.

The theory of the *M. d. u.*
Operandi of medicine which I wish to impress,
is simply this. "Whenever a medicinal substance
is applied to a susceptible portion of the body,
externally or internally, an action is excited
which is extended more or less, according to the
diffusibility of the properties of the substance,
or the degree of sympathetic connection which
the part may maintain with the body generally."
That this is the true mode by which medicines
produce their effects, is I think pretty evident.
We know very well that morbid impressions
made in a part are conveyed through the
medium of Sympathy, and it is therefore

[Faint, illegible handwriting on lined paper, likely bleed-through from the reverse side.]

per
in
was
pro
ful
the

sym
h
of
pro

very reasonable to suppose that salutary impressions should be extended in the same way. But the narrow limits to which I am necessarily confined prevent my going any further into the arguments by which this theory of the *Modus Operandi* of Medicine is supported. Suffice it to say that the doctrine accounts beautifully for many operations that take place in the human system. Thus when acrid spirit is exhibited in any quantity, the brain is almost instantaneously affected, and this effect cannot possibly be accounted for on any other principle than the sympathetic extension of the original local impression.

The reason why a medicine operates upon one particular part in preference to another cannot at all be explained

whether indeed it is necessary. Certain it is that every organ has its peculiar and appropriate stimulus: as light to the eye; sound to the ear, &c. The circumstance therefore, need not astonish us; and the doctrine of Sympathy is, not at all defective, on this account.

On the whole, this mode of explaining the operation of Medicines appears the most intelligible, rational and compatible with the present state of science. And accordingly the opinion is embraced by some of the most ingenious and scientific of Physiologists and Philosophers.

I have thus in as concise a manner as possible given a condensed account of the principal circumstances connected with the Modes of operating Medicines.

The subject it is true is intricate and altogether speculative, and I incur and may perhaps merit severe censure for engaging in it.

I cannot however conclude without making one more remark. — I am well aware that it has been considered by some a matter of no importance whether we understand the manner in which medicines operate or not. Such a doctrine however is the very bane of science. It gives open countenance to scepticism, and prostrates every ennobling sentiment of investigation and research. It encourages ignorance, hoists the flood-gates of error, and lights the torch of chicanery and empiricism. True it is that when we soar too high on the aerial pinions of theory and speculation, we are

liable to be led into error. But restrained
within its proper boundaries, I do maintain
that theorizing is perfectly safer and it is
the only possible means of explaining many
of the secret operations of nature, shrouded
as they are by the opaque comparison of obscurity.
Let the consideration then of former
achievements stimulate to a more ardent
enthusiasm, by which truth may be confirmed
and science benefited.
